1 Introduction

The Optical Music Recognition task is more complex than OCR. Despite to the availability of several commercial OMRs: SharpEye2, SmartScore, Photoscore, CapellaScan, etc., none of these is satisfactory in terms of precision and reliability. The efficiency declared by the each distributor is close to 90%, but this value is obtained only when quite regular music sheets are processed and the estimation is not always objective. In the character or face recognition field, there are many ground truth databases that enable recognition results to be evaluated automatically and objectively. At the present time, there is neither a standard database for music score recognition or a standard terminology. If a new recognition algorithm or system were proposed, it could not be compared with the other algorithms or systems since the results would have to be traditionally evaluated with different scores and different methods. Taking these facts into consideration, it is indispensable to make a master music score database that can be used to objectively and automatically evaluate the music score recognition system. At the same time a set of rules and metrics are needed in order to define what aspects have to be considered in the evaluation.

2 Evaluation methodologies for OMR application

To cope with the lack of standard methodologies, a study for the definition of OMR performance evaluation models has been conducted. Actually, the study is in progress and is focussed to monophonic music score. The chosen solution has been addressed in defining two evaluation methodologies.

2.1 EVALUATION OF BASIC SYMBOLS RECOGNITION

This is a low-level analysis where the recognition of each basic symbols and to consider them independently each other is measured. An elementary information is assigned to each symbol and its recognition constitutes the first step in the reconstruction of complete music symbols. In these terms, this kind of evaluation allows considering the capacity of the system in recognising elementary information. A set of basic symbols has been defined on the basis of examples considered as test images. For each category of symbols the following metrics have been defined:

1. The occurrence number E_i of expected symbols (*Expected*) for each category counted in the original score.
2. The occurrence number T_i of correct symbols (*True*), counted in the reconstructed score respect of the original score.
3. The occurrence number F_i of confused symbols (*False*), added or wrong symbols counted in the reconstructed score respect of the original score.
4. The occurrence number M_i of missed symbols (*Miss*), symbols not recognised but that are in the original score.
5. The measurement of each metric is done by counting basic symbols located in the original score and afterwards by repeating the counting in the reconstructed score.

Considering as:

- N the number of categories;
- $E_{tot} = \sum_{i=1}^N E_i$, the total number of expected basic symbols;

the following evaluation indexes have been defined:

1. Percentage Recognition Rate

$$T_R = \frac{\sum_{i=1}^N T_i}{E_{tot}} 100$$

2. Weighted Percentage Recognition Rate

$$TW_R = \frac{1}{E_{tot}} \frac{\sum_{i=1}^N p_i T_i}{\sum_{i=1}^N p_i} 100$$

where:

- p_i stands for the relevance (weight) given to each basic symbol. The range for weights is [1,10], where 10 means high relevance.

3. Percentage Confusion Rate (or Recognition Noise)

$$TC_R = \frac{\sum_{i=1}^N F_i}{E_{tot}} 100$$

The set of considered basic symbols is reported in the following table:

Symbol	Name	Symbol	Name
	Empty Note Head duration 4/4		Beam 1 (duration 1/8)
	Empty Note Head duration 2/4		Beam 2 (duration 1/16)
	Black Note Head duration 1/4 -> 1/64		Beam 3 (duration 1/32)
	Rest duration 4/4		Beam 4 (duration 1/64)
	Rest duration 2/4		Augmentation Dot
	Rest duration 1/4		Accent
	Rest duration 1/8		Number 1
	Rest duration 1/16		Number 2
	Rest duration 1/32		Number 3
	Rest duration 1/64		Number 4
	Barline Single		Number 5
	Barline Double		Number 6
	Barline End		Number 8
	Barline Start Refrain		Number 9
	Barline End Refrain		Number 12

	Sharp		Number 16
	Flat		Slur
	Natural		P (piano)
	Double Sharp		F (forte)
	Double Flat		Comma (breath)
	Treble Clef		C
	Bass Clef		Staccato
	Baritone Clef		Fermata
	Tenor Clef		Mordent
	Contralto Clef		Turn
	Mezzosoprano Clef		Grace Note
	Soprano Clef		Trill
	Hook 1 (duration 1/8)		Tenuto
	Hook 2 (duration 1/16)		
	Hook 3 (duration 1/32)		
	Hook 4 (duration 1/64)		

This set of symbol is not exhaustive, but it allows evaluating the performance of monophonic music score recognition. It could be extended to include other symbols or to divide a symbol in more symbols in order to improve the accuracy of the evaluation.

2.2 EVALUATION OF COMPLETE MUSIC SYMBOLS AND RELATIONSHIPS RECONSTRUCTION

The goal is to evaluate the capacity in recognising complete music symbols and music syntax. A complete music symbols is the final result in reconstructing relationships among basic symbols. Some basic symbols are at the same time complete music symbols (rests, clef), whereas others are elementary components (a piece of beam, an augmentation dot, etc...) of a more complex music symbol. Recognising a single basic symbol does not mean that music symbols will be correct, since from the point of view of final result the music symbol has to be identified and characterised by its music features and relationships with other symbols. The identification of a note head does not imply the complete note recognition, it is characterised by its pitch, duration, an accidental correctly assigned, if it is in a group of note, etc... The realisation of a beamed notes group is an index of the capability in reconstructing relationships among notes of the group. To this end, an evaluation set of complete music symbols and relationships among symbols have been defined and for each category the following metrics have been defined:

1. The occurrence number of *expected* N complete symbols or relationships for each category, they are counted in the original score.
2. The occurrence number of *correct* n_i complete symbols or relationships for each category, they are counted in the reconstructed score comparing it with the original score.

3. The occurrence number of *added* n_a complete symbols or relationships for each category, they are counted in the reconstructed score comparing it with the original score.
4. The occurrence number of *fault* n_f complete symbols or relationships for each category, they are counted in the reconstructed score comparing it with the original score.
5. The occurrence number of *missed* n_m complete symbols or relationships for each category, symbols or relationships not recognised but that are in the original score. They are counted in the reconstructed score comparing it with the original score.

For each category the following equation is valid:

$$N = n_t + n_f + n_m$$

This evaluation method extends the previous and is characterised by a more accurate analysis, in fact a music symbol or a relationship is considered correct if basic symbols and music symbols that are involved in the relationship are correct. For this reason, this kind of evaluation is more severe than the previous one.

Considering as:

- M the total number of symbols and relationships;
- $E_{tot} = \sum_{i=1}^M N_i$, the total number of expected symbols and relationships;

the following evaluation indexes have been defined:

1. Percentage Reconstruction Rate

$$T_{Rec} = \frac{\sum_{i=1}^M n_t^{(i)}}{E_{tot}} 100$$

2. Weighted Percentage Reconstruction Rate

$$TP_{Rec} = \frac{1}{E_{tot}} \frac{\sum_{i=1}^M p_i n_t^{(i)}}{\sum_{i=1}^M p_i} 100$$

where:

- p_i stands for the relevance (weight) given to each basic symbol or relationship. The range for weights is $[1,10]$, where 10 means high relevance.

3. Percentage Reconstruction Error

$$E_{Rec} = \frac{\sum_{i=1}^M n_f^{(i)} + n_a^{(i)} + n_m^{(i)}}{E_{tot}} 100$$

The list of categories used during the test is reported below. For each category is described how to measure metrics. This evaluation set is not exhaustive for all genre of music score, it could be extended in order to include more aspects (structural, symbolic, etc...). The proposed list is able to describe the monophonic music score and relationships, and the most important and frequent symbols.

Note with pitch and duration

The aim is to evaluate the note reconstruction correctness in terms of pitch and duration. It has to be considered:

- *Correct*, when its pitch and duration are correct.
- *Fault*, when its pitch or duration is wrong;
- *Miss*, when the note shape is not in the reconstructed score;

- *Add*, when the note shape is not in the original score.

Rests

The aim is to evaluate the recognition of rests. It has to be considered:

- *Correct*, when the rest duration is correct.
- *Fault*, when the rest duration is wrong;
- *Miss*, when the rest shape is not in the reconstructed score;
- *Add*, when the rest shape is not in the original score.

Note with accidentals

The aim is to evaluate the association of accidentals (sharp, flat, double sharp, natural, double flat) with a note. It has to be considered:

- *Correct*, when the accidental has been linked correctly to the note.
- *Fault*, when the accidental it has been linked to the note but it is wrong;
- *Miss*, when the accidental has been not linked to the related note;
- *Add*, when the accidental has been linked to a note and the original note has not the accidental.

Groups of beamed notes

The aim is to evaluate the capability in reconstructing beamed notes. The evaluation is focussed in the realisation of notes groups. It has to be considered:

- *Correct*, when the group has been realised;
- *Fault*, it is not defined since it is linked to the correctness of notes reconstruction (pitch and duration);
- *Miss*, when the beaming connection among notes has been not rebuilt in the reconstructed score;
- *Add*, when the beaming connection is not in the original score.

Time signature and time change

The aim is to evaluate the capability in identifying and reconstructing the time indication by recognised numbers involved in the fraction. It has to be considered:

- *Correct*, when numerator and denominator are correct;
- *Fault*, when numerator or denominator are wrong;
- *Miss*, when the time signature is not present in the reconstructed score;
- *Add*, when the time signature is not present in the original score.

Key signature and key signature change

The aim is to evaluate the capability in identifying and reconstructing the key signature (tonality). The tonality is linked to the number of accidentals used in representing the key signature. It has to be considered:

- *Correct*, when number of sharps or flats (and possible naturals involved in the tonality change) are correct;
- *Fault*, when the number of accidentals symbols is wrong;
- *Miss*, when the key signature is not present in the reconstructed score;
- *Add*, when the key signature is not present in the original score.

Symbols below or above notes

The aim is to evaluate the capability in identifying and linking ornaments symbols and accents (staccato, accent, turn, mordent, trill, tenuto, etc...). It has to be considered:

- *Correct*, when the linked symbol is correct;
- *Fault*, when the linked symbol is wrong;
- *Miss*, when the symbol is not present in the reconstructed score;
- *Add*, when the symbol is not present in the original score.

Grace notes

The aim is to evaluate the capability in recognising grace notes: acciaccatura and appoggiatura are related to a single symbol while multiple grace notes define a group of notes. The multiple notes are considered a unique symbol. It has to be considered:

- *Correct*, when grace notes are correct all the features (pitch, duration, type of grace note) are perfectly reconstructed;
- *Fault*, when a feature among pitch, duration and type of grace note is wrong;
- *Miss*, when grace notes are not present in the reconstructed score;
- *Add*, when grace notes are not present in the original score.

Slurs and bends

The aim is to evaluate the reconstruction of horizontal symbols: slurs (and ties) and bends. It has to be considered:

- *Correct*, when the start and the end note are correct;
- *Fault*, when the start or the end note is not correct;
- *Miss*, when the slur or bend is not present in the reconstructed score;
- *Add*, when the slur or bend is not present in the original score.

Augmentation dots

The aim is to evaluate the augmentation dots linking to notes. In presence of multiple dots, they have to be counted one by one. It has to be considered:

- *Correct*, when the augmentation dot has been linked to the note correctly;
- *Fault*, this condition is equivalent to the *Miss* case;
- *Miss*, when the augmentation dot has not been linked to the note;
- *Add*, when the augmentation dot is not present in the note of the original score.

Clefs

The aim is to evaluate the recognition of clefs and clef changes. A symbol can indicate different clefs, for instance Alto clef and Baritone clef. In these cases the *position* in the staff and the *shape* have to be taken in account. It has to be considered:

- *Correct*, when shape and position are correct;
- *Fault*, when shape or position are not correct;
- *Miss*, when the clef is not present in the reconstructed score;
- *Add*, when the clef is not present in the original score.

Irregular notes groups

The aim is to evaluate the capability in recognising tuplets. An irregular group is a set of notes not necessarily beamed and with a numeric indication that defines the kind of tuplet. It has to be considered:

- *Correct*, when group of note is in effect an irregular group and the numeric indication is correct;
- *Fault*, when the group of notes is in effect an irregular group but the numeric indication is not correct;
- *Miss*, when the irregular group has not been recognised;
- *Add*, when the identified group is not an irregular group in the original score.

Number of measures

The aim is to evaluate the capability in recognising the bar line and the number of measures. The recognition of bar lines could generate different error in measure reconstruction: fusion of measures, adding empty measures, measure fragmentation. It has to be considered:

- *Correct*, when a measure of the original score is detectable in the reconstructed score;
- *Fault*, this condition is equivalent to the *Miss* case;
- *Miss*, when a measure of the original score is not detectable in the reconstructed score (the missed recognition of a bar line could generate the fusion of two consecutive measure. In this case a measure is lost and then it has to be counted as *Miss*, while the reconstructed one could be considered right);
- *Add*, when the measure is not present in the original score or a measure has been divided in two measures.

Number of staves

The aim is to evaluate the capability in recognising staves. It has to be considered:

- *Correct*, when a measure of the original score is detectable in the reconstructed score;

- *Fault*, when the staff has different features (number of lines);
- *Miss*, when the staff has been not identified;
- *Add*, when the staff is not the original score.

3 Recognition costs

The evaluation of the recognition system performance is not only reduced to a simple counting of correct, fault, missed, added symbols, but it has to take in account the work needed to correct mistakes, to re-format a measure, to rebuild music symbols at the end of recognition. Many of these operations are strictly connected with the music notation format used for representing the music information and the capacity of the adopted recognition system and music editor. An OMR system could be considered the best if it minimises the time needed for the correction. To evaluate the reconstruction of a score, it is needed to compare the original score with the rebuilt score by the system in order to check for mistakes, missed or added music symbols or relationship among symbols. The check is needed even if the rate is 100%, since there is not any warranty what has been rebuilt is really correct. Then, the correct symbols have to be also considered in order to validate their reconstruction.

These considerations highlight the need to define different cost as:

- Average editing cost C_i to insert or to create a new symbol or relationship by means of a music editor.
- Average verification cost C_v to check the correctness of music symbols or relationships.
- Average cost to correct mistakes $C_f = \hat{C}_f + C_v$, it is defined as the sum of the proper cost \hat{C}_f to correct the mistakes and the average verify cost.
- Average cost to delete the added symbols or relationship $C_a = \hat{C}_a + C_v$, it is defined as the sum of the proper cost \hat{C}_a to delete the symbol or relationship and the average verify cost
- Average cost to resume missed symbols or relationship $C_m = \hat{C}_m + C_v$, it is defined as the sum of the proper cost to edit \hat{C}_m the symbol or relationship and the average verify cost
- Average cost to check correct symbols or relationship $C_t = C_v$, it is equal to the average verify cost.

The last four costs are strictly connected to the performance of the OMR system, the editing cost and the verify cost depend on the usability of the used music editor, the skill of the user for checking the symbols. These costs allow evaluating if it is convenient or not to adopt an automatic recognition in an objective manner, since it is possible to evaluate and compare the real cost for the automatic system and the manual writing by means a music editor.

Recognition Gain – To evaluate a measure of the convenience in using an OMR system, we define the *Recognition Gain* as following:

$$G = \frac{C_0}{C_{OMR}} \geq \gamma \quad (1.1)$$

Where

- C_0 is the total cost to transcribe a music score by means of a music editor.
- C_{OMR} is the correction cost required to adjust the transcribed score when an OMR system is adopted.
- $\gamma \geq 1$ is the desired gain to have convenience.

The \hat{C}_f , \hat{C}_a , and \hat{C}_m costs are typically editing costs. They can be written in terms of the average editing cost C_i introducing constants of proportionality α_f , α_a , and α_m :

$$\hat{C}_f = \alpha_f C_i \quad \hat{C}_a = \alpha_a C_i \quad \hat{C}_m = \alpha_m C_i \quad (1.2)$$

C_0 and C_{OMR} can be related to C_i as following:

- if n_t is the number of correct music symbols and relationships, n_f is the number of incorrect music symbols and relationships, n_a is the number of added music symbols and relationships and n_m is the number of missed music symbols and relationships:

$$C_{OMR} = n_f C_f + n_a C_a + n_m C_m + n_t C_t \quad (1.3)$$

- if N is the number of music symbols and relationship to be transcribed and $k > 1$ is a constant of proportionality that takes into account further editing operations (page definition and formatting, number of staves setting up, number of measure creation, etc...) and the music symbol reading from the original score:

$$C_0 = kNC_i \quad (1.4)$$

Since N is the number of symbols and relationships to be written, the following equation is valid:

$$N = n_t + n_m + n_f \quad (1.5)$$

By means of the equations (1.1), (1.2), (1.3) and (1.4), the verify cost is given by:

$$C_v \leq \frac{kNC_i}{\gamma(N + n_a)} - \frac{(n_f\alpha_f + n_f\alpha_f + n_f\alpha_f)C_i}{N + n_a} \quad (1.6)$$

If the recognition is 100%, the verification cost depends only on the editing cost:

$$C_v \leq \frac{kC_i}{\gamma} = C_v^0 \quad (1.7)$$

The verification cost is strictly linked to the capabilities of the music editor, in terms of data entry velocity. In the real case, introducing the percentage taxes:

$$k_f = \frac{n_f}{N} \quad k_a = \frac{n_a}{N} \quad k_m = \frac{n_m}{N}$$

the (1.6) becomes:

$$C_v \leq C_v^0 \frac{1}{(1 + k_a)} - \frac{(k_f\alpha_f + k_a\alpha_a + k_m\alpha_m)C_i}{1 + k_a} \quad (1.8)$$

The equation (1.8) shows the link between the verification cost and all contributes due to the recognition, where for each improvement of the recognition system the bound for the verification cost increases, whereas for each improvement of the editing the bound decreases.

4 Results

Three applications have been selected in order to compare the performance in the score recognition: SharpEye2 (Visiv), SmartScore (MusiTek) and O³MR (developed at the DSI – University of Florence).

Definition of test – The missing of a ground truth databases conditioned the choice of tests, to cope with this lack, seven images have been selected from the archive of collected images at the DSI. The chosen music scores have the following features:

- Monophonic music.
- Font variability.
- Music symbols frequently used in the classic music repertory.
- Variable density of music symbols.
- Irregular groups (triplets, etc.).
- Small note with or without accidentals (grace notes).
- Different barlines (start and end refrain, end score, single barline and double barline).
- Clef and time change.
- Ornaments (mordent, turn, and trill).

Performance Evaluation based on basic symbols recognition

Figures 1,2 and 3 show evaluation tables respectively for SmartScore, O³MR and SharpEye2. In each table results of measurements are reported. The table is divided in sub tables and each of them in two sections: the

expected values column (symbols counted in the original score) and columns under the **found** voice (symbols counted in the reconstructed score). In the found section:

- The **Total** column reports the number of occurrences for each basic symbol.
- The **True** column reports the number of occurrences for correct basic symbols.
- The **Fault** column reports the number of occurrences for confused basic symbols.
- The **Miss** column reports the number of occurrences for missed basic symbols.

The **W** column reports values given to weights and associated to each basic symbol. Values in the tables show that:

- SmartScore loses information and the number of missing symbol is greater than confused symbols. The accent symbol has been never recognised, some identification problems with time signatures, rests with duration less than 1/8 and slurs. It adds whole notes, augmentation dots and staccato symbols. Mordent, trill and fermata seem to be not managed.
- SharpEye2 shows a best performance, but at the same time it loses information. It adds a less symbols than the other two software. It is able to reconstruct slurs and recognise trill, fermata and grace notes. Some problems with Baritone clef have been detected.
- O³MR loses information, since in the current version it does not manage symbols such as fermata, trill, staccato, mordent and turn. The high value of confusion is mainly due to the difficulty in slur reconstruction.

Observing the graphics reported in Figure 4, SharpEye provides in general the best performance. The O³MR is comparable with SmartScore, but it introduces less symbols than SmartScore.

Performance Evaluation based on complete music symbols and relationships reconstruction

Figure 5 shows evaluation tables respectively for SmartScore, O³MR and SharpEye2. Each table collects sub tables that refer to examples to test. Each sub table consists of:

- The **Expected** column where the number of counted occurrences for the expected symbol or relationship has been reported (N_i). The counting has been done on the original score.
- The **True** column where the number of counted occurrences for the correct symbol or relationship has been reported (n_i). The counting has been done on the reconstructed score.
- The **Add** column where the number of counted occurrences for the added symbol or relationship has been reported (n_a). The counting has been done on the reconstructed score.
- The **Fault** column where the number of counted occurrences for the fault symbol or relationship has been reported (n_f). The counting has been done on the reconstructed score.
- The **Miss** column where the number of counted occurrences for the missed symbol or relationship has been reported (n_m). The counting has been done on the reconstructed score.

The **W** column reports values given to weights and associated to each basic symbol.

Tables show that:

- SmartScore introduces errors in notes reconstruction and adds notes. It detects triplets, but the main tendency is to make mistakes. SmartScore seems to detect triplets by analysing the time consistence of the measure and not by recognising the number that characterises them. It has difficulty with slurs, time signature change and key signatures.
- SharpEye 2 does not introduce notes, it has some problems with triplets. Differently by SmartScore, SharpEye seems to recognise the triplet by detecting the number that characterises it. In the grace notes detection, it does not discriminate appoggiatura from acciaccatura, it considers only grace notes as appoggiatura.
- The main limits for O³MR are due to the recognition of slurs, triplets, grace notes and ornaments symbols. It introduces rests when the segmentation provided a wrong decomposition of symbol, whereas it adds less symbols than SmartScore.

Observing graphics reported in Figure 6, SharpEye provides in general the best performance. The O³MR is yet comparable with SmartScore.

Notes and rests recognition

The recognition of notes and rests is the most important requirement that an OMR system has to respect. They are considered the most important music symbols, and their recognition has to be robust and to provide

a high performance. The evaluation of note recognition has to take into account the pitch and the duration. All examples have been considered and values reported in tables of Figure 5 (*Evaluation based on complete music symbols and relationships reconstruction*) have been used. The evaluation has been performed by considering the percentage rate for correct, incorrect, missed and added notes and rests. They have defined as following:

Percentage rate for correct (True) symbols

$$TT_{Rec} = \frac{\sum_{i=1}^7 n_t^{(i)}}{\sum_{i=1}^7 N_i} 100$$

Percentage rate for incorrect (Fault) symbols

$$TF_{Rec} = \frac{\sum_{i=1}^7 n_f^{(i)}}{\sum_{i=1}^7 N_i} 100$$

Percentage rate for missed (Miss) symbols

$$TM_{Rec} = \frac{\sum_{i=1}^7 n_m^{(i)}}{\sum_{i=1}^7 N_i} 100$$

Percentage rate for added (Add) symbols

$$TA_{Rec} = \frac{\sum_{i=1}^7 n_a^{(i)}}{\sum_{i=1}^7 N_i} 100$$

N_i stands for the total number of expected symbols for the each example. The percentage values are reported in the following tables:

Note recognition (pitch & duration)	SmartScore	SharpEye2	O ³ MR
Correct Notes (TT_{Rec})	95.68%	96.67%	97.24%
Incorrect Notes (TF_{Rec})	2.29%	1.25%	1.72%
Missed Notes (TM_{Rec})	2.03%	2.08%	1.04%
Added Notes (TA_{Res})	2.44%	0.21%	1.20%

Rests recognition	SmartScore	SharpEye2	O ³ MR
Correct Rests (TT_{Rec})	38.54%	81.77%	94.79%
Incorrect Rests (TF_{Rec})	0.00%	2.60%	0.52%
Missed Rests (TM_{Rec})	61.46%	15.63%	4.69%
Added Rests (TA_{Rec})	8.85%	0.00%	8.85%

Tables show the O³MR capability in recognising notes and rests. In particular, the recognition rate for rests is the highest, with a difference of 13.02% with SharpEye2 and 56.25% with SmartScore. In terms of corrections to perform after the reconstructing phase, the O³MR provides a behaviour comparable with SharpEye2. Rests, added by O³MR, are due to segmentation errors. They generate incorrect basic symbols that are recognised as rests. This is a limit for the actual version of the O³MR system.

5 Conclusion

The problem of Optical Music recognition tools assessment has been discussed. The lack of standard methodologies does not allow comparing objectively the existing OMR tools. For this reason the study and approaches for the definition of OMR performance evaluation models has been described. Two evaluation methodologies have been proposed: the evaluation based on basic symbols and the evaluation based on complete music symbols and their relationships. These methodologies have been used to compare three OMR tools: SharpEye2, SmartScore and O³MR. The final results show that SharpEye2 is the tool with best performances. It also manages more symbols. SmartScore and O³MR are comparable, but in terms of notes and rests recognition O³MR is more robust than SmartScore.

A evaluation on costs needed to polish the reconstructed score from mistakes has been described. The most important cost is the verification cost. It is always needed, even if the OMR tool recognises perfectly, since the correctness of each music symbol has been verified. If the verification cost is less than editing cost then we have a gain in using the OMR tools.

SmartScore		W		Example 1			Example 2			Example 3			Example 4			Example 5			Example 6			Example 7																
Basic Symbols		Expected	Found	Total	True	Fault	Miss	Expected	Found	Total	True	Fault	Miss	Expected	Found	Total	True	Fault	Miss	Expected	Found	Total	True	Fault	Miss	Expected	Found	Total	True	Fault	Miss							
10	Empty Note Head duration 4/4	1	9	1	8	0	0	1	5	1	4	0	0	0	4	0	4	0	0	0	0	0	0	0	0	0	0	4	0	4	0	1	0	1	0	0
